p for trend	0.04	0.93	0.84

^aJoint models for multiple outcomes and multiple cycles per woman were used. Models adjusted for study site, study phase, race/ethnicity, previous livebirth, maternal age, BMI, smoking status, ampules of gonadotropins, protocol, ICSI, number of embryos transferred, and primary infertility diagnosis.

^bThere were 827 cycles with serum samples analyzed for PCB concentrations. However, due to missing covariates, only 774 cycles from 720 women contributed to the multivariate analysis. Missing ethnicity, infertility diagnosis, and previous live birth were recoded as a separate category so that cycles that were missing this information were in the multivariate models. If a cycle was missing any other covariate, that cycle was dropped from the multivariate analysis. Specifically, 13 cycles were missing lipids, 2 cycles were missing amps of gonadatropins, 32 cycles were missing number of embryos transferred, and 6 cycles were missing BMI
